**BASIC PRINCIPLES**

Pohl’s wheel or rotating (torsional) pendulum allows for the investigation of simple harmonic rotary oscillation. The only forces acting on the wheel are the restoring torque provided by a spiral spring and damping torque supplied by means of an eddy current brake with an adjustable current.

The equation of motion for the angle of deflection $\varphi$ of a freely oscillating, but damped torsional pendulum is as follows:

\[
\frac{d^2\varphi}{dt^2} + 2 \cdot \delta \cdot \frac{d\varphi}{dt} + \omega_0^2 \cdot \varphi = 0
\]

where \( \delta = \frac{k}{2J} \quad \omega_0^2 = \frac{D}{J} \)

\( J \): moment of inertia
\( D \): spring constant
\( k \): damping coefficient

As long as the damping is not excessive and the condition $\delta < \omega_0$ is fulfilled, the equation of motion has the following solution:

\[
\varphi(t) = q_0 \cdot e^{-\delta t} \cdot \cos(\omega t + \psi)
\]

where \( \omega = \sqrt{\omega_0^2 - \delta^2} \).

The initial amplitude $q_0$ and the phase angle $\psi$ are arbitrary parameters which are dependent on the deflection and speed of the rotary pendulum at a time $t = 0$. The pendulum will therefore move back and forth with the following period of oscillation:

\[
T = \frac{2\pi}{\omega}
\]

The amplitude of the oscillations decreases over time according to the following equation:

\[
\dot{\varphi}(t) = q_0 \cdot e^{-\delta t}
\]

In this experiment oscillations are investigated with various levels of damping, which can be set up by varying the current to the eddy current brake. The period of oscillation is measured with the aid of a stopwatch. It will be shown that the period of oscillation is not dependent on the initial deflection or velocity.

In order to determine the degree of damping the limits of each oscillation to the left and right are taken down. This simplifies the analysis since if such points are taken as the time zero, then the initial velocity will be zero.

**EVALUATION**

In equation (4) the amplitude of the oscillation is defined as a positive value. This implies that the absolute values for the limits of the motion to the left and right should be considered. If the natural logarithms of these values are plotted against time, a straight line with a gradient $\delta$ should be obtained. In fact certain deviations from such linear behaviour will be observed, since the force of friction is not exactly proportional to the speed as assumed here.
